Client-Server Programming

Figure 1
HTTP

SMTP

Proprietary Protocol

What is an Application-Level Protocol?

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

- **A set of rules** that specify how the application components (e.g. clients and servers) **communicate with each other**. Typically, a protocol defines at least:

  - **Which transport-layer protocol** is used to exchange application-level messages. (e.g. TCP for HTTP)

  - **Which port number(s)** to use (e.g. 80 for HTTP)

  - **What kind of messages** are exchanged by the application components and the **structure** of these messages.

  - The **actions** that need to be taken when these messages are received and the **effect** that is expected.

  - Whether the protocol is **stateful** or **stateless**. In other words, whether the protocol requires the server to manage a session for every connected client.

Network Programming

Given a application-level protocol,

how can we implement a client and server in a particular programming language?

What abstractions, APIs, libraries are available to help us do that?

We know about TCP, UDP and IP. But how can we benefit from these protocols in our code?
The TCP Protocol

TCP

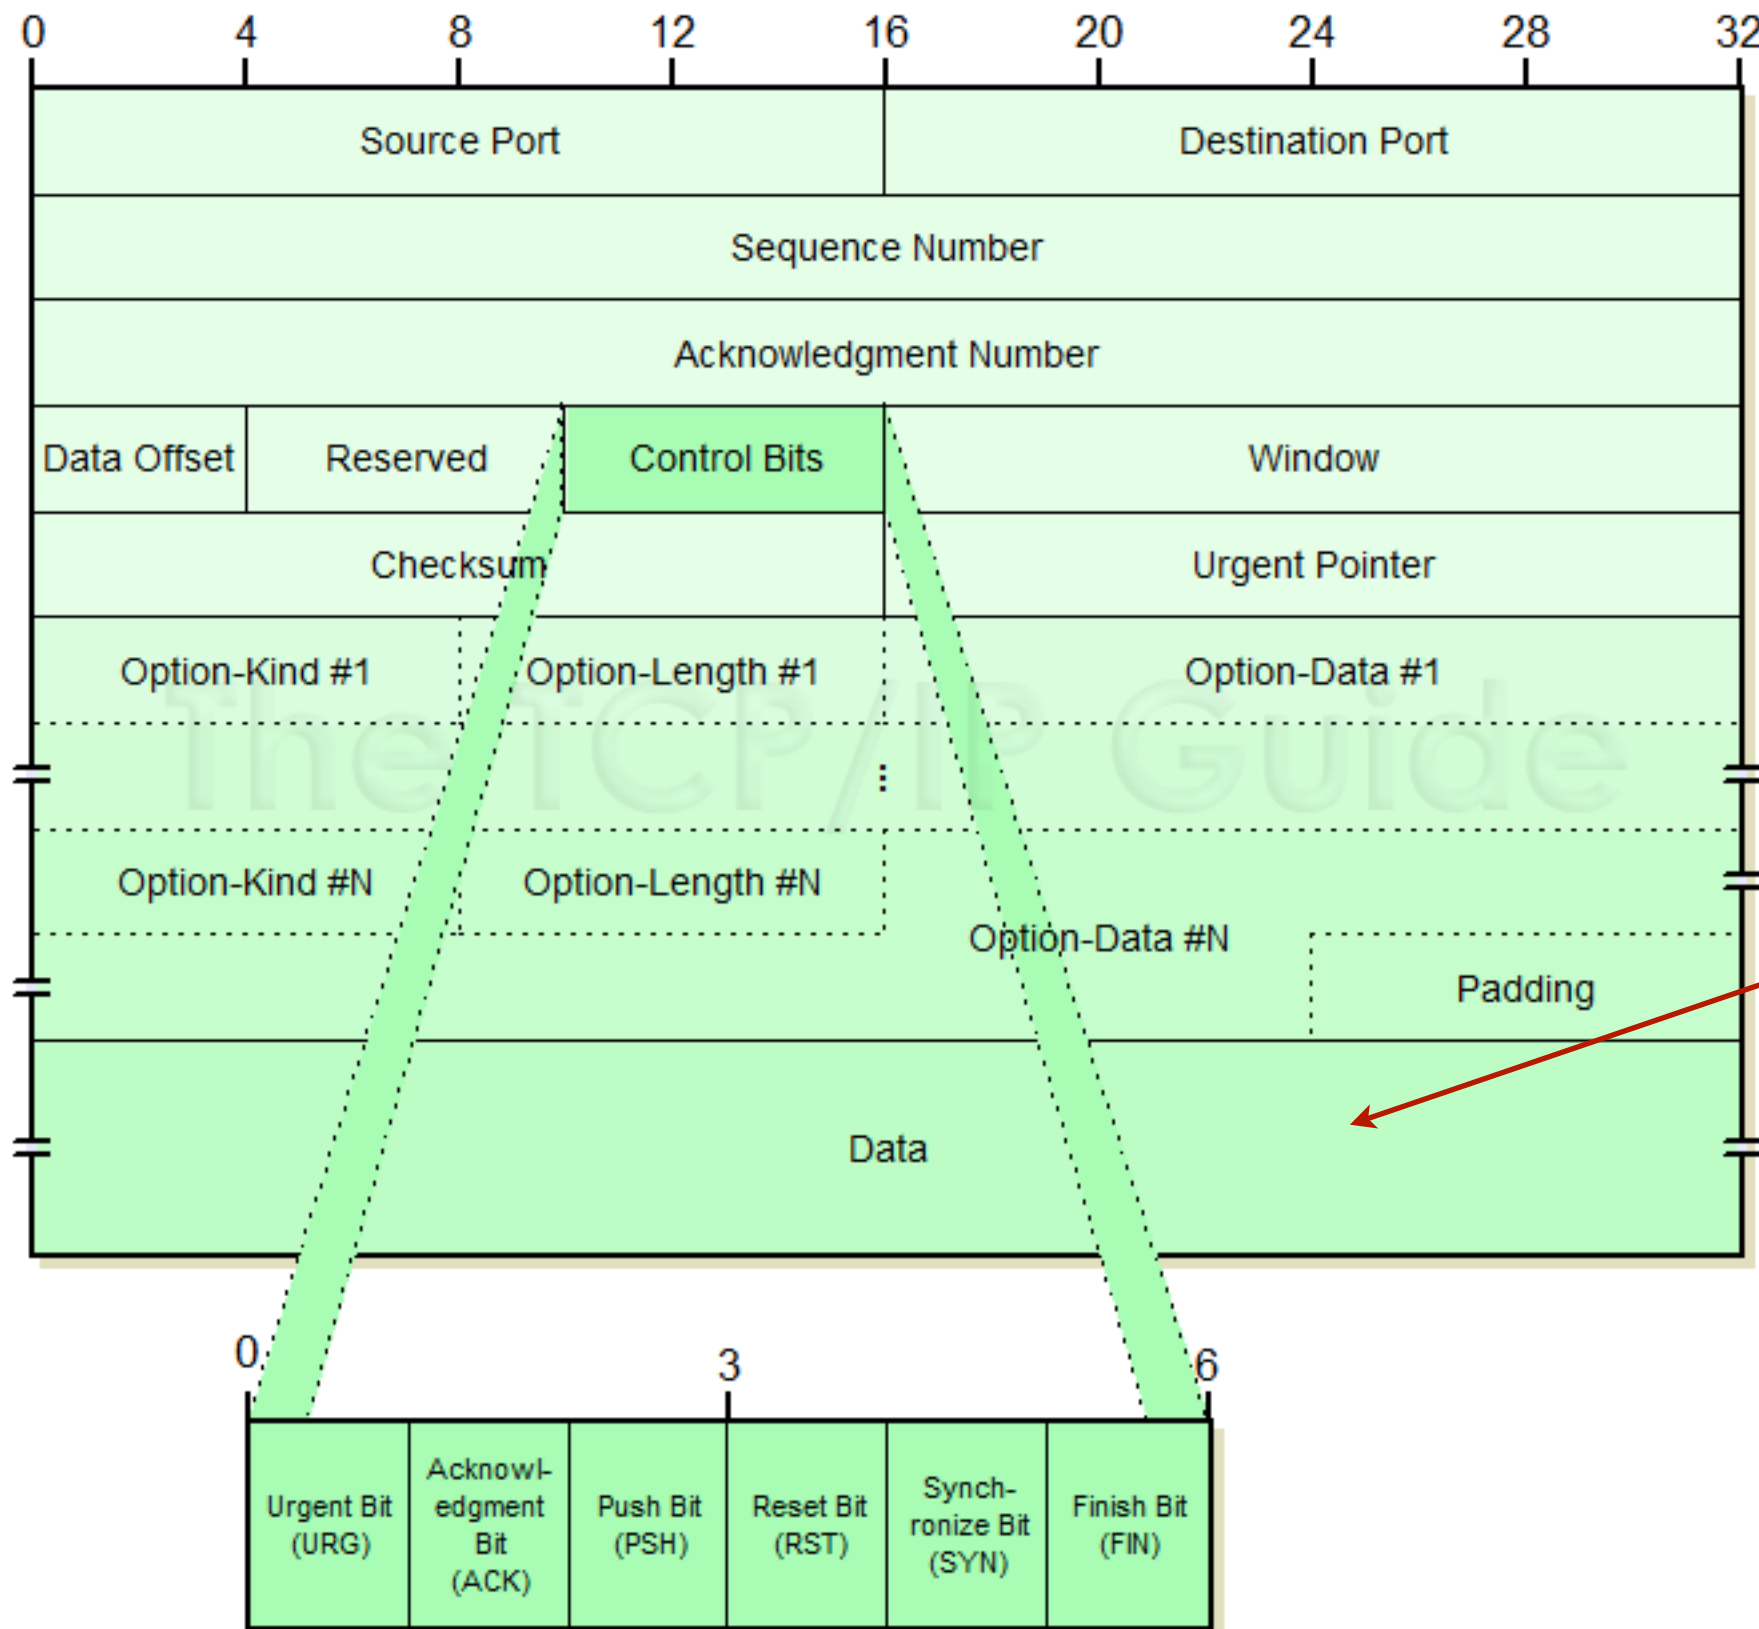

UDP

Transport Protocols

- Both TCP and UDP are **transport protocols**.

- This means that they make it possible for **two programs** (i.e. applications, processes) possibly running on **different machines** to **exchange data**.

- The two protocols also make it possible for several programs to **share the same network interface**. They use the notion of **port** for this purpose.

- TCP and UDP define the **structure of messages**. With TCP, messages are called **segments**. With UDP, messages are used **datagrams**.

- The structure of TCP segments (**number and size of headers**) is more complex than the structure of UDP datagrams.

- Both TCP segments and UDP datagrams can be **encapsulated in IP packets**. In that case, we say that the **payload** of the IP packet is a TCP segment, respectively a UDP datagram.

Transport Protocols

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

- TCP provides a **connection-oriented service.** The client and the server first have to establish a connection. They can then exchange data through a **bi-directional stream of bytes**.

- TCP provides a **reliable data transfer service.** It makes sure that all bytes sent by one program are received by the other. It also preserves the **ordering** of the exchanged bytes.

- UDP provides a **connectionless service.** The client can send information to the server at any time, **even if there is no server listening.** In that case, the information will simply be lost.

- UDP **does not guarantee the delivery** of datagrams. It is possible that a datagram sent by one client will never reach its destination. The ordering is not guaranteed either.

- TCP supports **unicast** communication. UDP supports **unicast**, **broadcast** and **multicast** communication. This is useful for **service discovery**.

The Socket API

Network Programming

Given a application-level protocol,

how can we implement a client and server in a particular programming language?

What abstractions, APIs, libraries are available to help us do that?

We know about TCP, UDP and IP. But how can we benefit from these protocols in our code?

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

The Socket API

- The Socket API is a **standard interface**, which defines **data structures** and **functions** for writing client-server applications.

- It has originally been developed in the context of the Unix operating system and specified as a C API.

- It is now available **across nearly all operating systems and programming environments**.

```
<sys/socket.h>
```

```
int       accept(int socket, struct sockaddr *address,
              socklen_t *address_len);
int       bind(int socket, const struct sockaddr *address,
              socklen_t address_len);
int       connect(int socket, const struct sockaddr *address,
              socklen_t address_len);
int       getpeername(int socket, struct sockaddr *address,
              socklen_t *address_len);
int       getsockname(int socket, struct sockaddr *address,
              socklen_t *address_len);
int       getsockopt(int socket, int level, int option_name,
              void *option_value, socklen_t *option_len);
int       listen(int socket, int backlog);
ssize_t recv(int socket, void *buffer, size_t length, int flags);
ssize_t recvfrom(int socket, void *buffer, size_t length,
              int flags, struct sockaddr *address, socklen_t *address_len);
ssize_t recvmsg(int socket, struct msghdr *message, int flags);
ssize_t send(int socket, const void *message, size_t length, int flags);
ssize_t sendmsg(int socket, const struct msghdr *message, int flags);
ssize_t sendto(int socket, const void *message, size_t length, int flags,
              const struct sockaddr *dest_addr, socklen_t dest_len);
int       setsockopt(int socket, int level, int option_name,
              const void *option_value, socklen_t option_len);
int       shutdown(int socket, int how);
int       socket(int domain, int type, int protocol);
int       socketpair(int domain, int type, int protocol,
              int socket_vector[2]);
```

Using the Socket API for a TCP **Server**

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

1. Create a "receptionist" **socket**

2. **Bind** the socket to an IP address / port

3. Loop
   3.1. **Accept** an incoming connection (**block** until a client arrives)
   3.2. Receive a new socket when a client has arrived
   3.3. **Read** and **write** bytes through this socket, communicating
         with the client
   3.4. **Close** the client socket (and go back to listening)

4. **Close** the "receptionist" socket

Using the Socket API for a TCP **Client**

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

1. Create a **socket**

2. Make a **connection request** on an IP address / port

3. **Read** and **write** bytes through this socket, communicating with the client

4. **Close** the client socket

Using the Socket API

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

Port ???

Network Interface 1.1

Process A

Host 1 (client)

```
// Makes a connection request on port 80
Socket socket = new Socket("host2", 8080);
```

```
InputStream fromServer = socket.getInputStream();
OutputStream toServer = socket.getOutputStream();
```

```
// Listen on port 8080
ServerSocket serverSocket = new ServerSocket(8080);

// Wait until a client makes a connection request...
Socket commSocket = serverSocket.accept();
```

```
InputStream fromClient = commSocket.getInputStream();
OutputStream toClient = commSocket.getOutputStream();
```

Example: **05-DumbHttpClient**

Code walkthrough

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

**establish a connection
with server**

```java
public void sendWrongHttpRequest() {
    Socket clientSocket = null;
    OutputStream os = null;
    InputStream is = null;

    try {
        clientSocket = new Socket("www.heig-vd.ch", 80);
        os = clientSocket.getOutputStream();
        is = clientSocket.getInputStream();

        String malformedHttpRequest = "Hello, sorry, but I don't speak HTTP...\r\n\r\n";
        os.write(malformedHttpRequest.getBytes());

        ByteArrayOutputStream responseBuffer = new ByteArrayOutputStream();
        byte[] buffer = new byte[BUFFER_SIZE];
        int newBytes;
        while ((newBytes = is.read(buffer)) != -1) {
            responseBuffer.write(buffer, 0, newBytes);
        }

        LOG.log(Level.INFO, "Response sent by the server: ");
        LOG.log(Level.INFO, responseBuffer.toString());
    } catch (IOException ex) {
        LOG.log(Level.SEVERE, null, ex);
    } finally {

    }
}
```

...

**get streams to send and
receive bytes**

**read bytes sent by the
server until the
connection is closed**

Example: **04-StreamingTimeServer**

Code walkthrough

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

bind on TCP port

block until a client makes a connection request

we want to exchange characters with the clients (we should specify the encoding!)

we make sure to flush the buffer, so that characters are actually sent!

```java
ServerSocket serverSocket = null;
Socket clientSocket = null;
BufferedReader reader = null;
PrintWriter writer = null;

try {
    serverSocket = new ServerSocket(listenPort);
    logServerSocketAddress(serverSocket);
    clientSocket = serverSocket.accept();

    logSocketAddress(clientSocket);
    reader = new BufferedReader(new InputStreamReader(clientSocket.getInputStream()));
    writer = new PrintWriter(clientSocket.getOutputStream());

  for (int i = 0; i < numberOfIterations; i++) {
      writer.println(String.format("{'time' : '%s'}", new Date()));
      writer.flush();
      LOG.log(Level.INFO, "Sent data to client, doing a pause...");
      Thread.sleep(pauseDuration);
  }
} catch (IOException | InterruptedException ex) {
  LOG.log(Level.SEVERE, ex.getMessage());
} finally {
  reader.close();
  writer.close();
  clientSocket.close();
  serverSocket.close();
}
```

Running and interacting with network apps on Vagrant

How to use Vagrant?

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

```
Usage: vagrant [options] <command> [<args>]

    -v, --version                       Print the version and exit.
    -h, --help                          Print this help.

Common commands:
    box             manages boxes: installation, removal, etc.
    connect         connect to a remotely shared Vagrant environment
    destroy         stops and deletes all traces of the vagrant machine
    global-status   outputs status Vagrant environments for this user
    halt            stops the vagrant machine
    help            shows the help for a subcommand
    init            initializes a new Vagrant environment by creating a Vagrantfile
    login           log in to Vagrant Cloud
    package         packages a running vagrant environment into a box
    plugin          manages plugins: install, uninstall, update, etc.
    provision       provisions the vagrant machine
    rdp             connects to machine via RDP
    reload          restarts vagrant machine, loads new Vagrantfile configuration
    resume          resume a suspended vagrant machine
    share           share your Vagrant environment with anyone in the world
    ssh             connects to machine via SSH
    ssh-config      outputs OpenSSH valid configuration to connect to the machine
    status          outputs status of the vagrant machine
    suspend         suspends the machine
    up              starts and provisions the vagrant environment
    version         prints current and latest Vagrant version
```

The Vagrantfile

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

**what kind of "base" box
do we want to use**

```ruby
# -*- mode: ruby -*-
# vi: set ft=ruby :

# Vagrantfile API/syntax version. Don't touch unless you know what you're doing!
VAGRANTFILE_API_VERSION = "2"

Vagrant.configure(VAGRANTFILE_API_VERSION) do |config|
  config.vm.box = "phusion/ubuntu-14.04-amd64"
  config.vm.network "private_network", ip: "192.168.42.42"

  config.vm.provision "shell", path: "provision.sh", privileged: false

  # config.vm.network "forwarded_port", guest: 80, host: 8080
  # config.ssh.forward_agent = true
  # config.vm.synced_folder "../data", "/vagrant_data"

  config.ssh.forward_x11 = true

  # config.vm.provider "virtualbox" do |vb|
  #   # Don't boot with headless mode
  #   vb.gui = true
  #
  #   # Use VBoxManage to customize the VM. For example to change memory:
  #   vb.customize ["modifyvm", :id, "--memory", "1024"]
  # end

end
```

**the IP address assigned
to the VM**

**this script is executed at
"provisioning time"**

**PAT: localhost:8080 will be
forwarded to
192.168.42.42:80**

**(additional) shared folders; by default, the host
directory containing the Vagrantfile is available
under /vagrant in the VM**

```
config.vm.network "private_network", ip: "192.168.42.42"
config.vm.network "forwarded_port", guest: 9907, host: 4207
```

Network

Another laptop (10.192.95.122)

```
$ telnet 10.192.95.121 4207
```

Your laptop (10.192.95.121)

```
$ telnet 192.168.42.42 9907

La commande **lsof**

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

```
NAME
      lsof - list open files

SYNOPSIS
      lsof  [ -?abChKlnNOPRtUvVX ] [ -A A ] [ -c c ] [ +c c ] [ +|-d d ] [ +|-D D ] [ +|-e s ] [ +|-f [cfgGn] ] [ -F [f] ] [ -g [s] ] [ -i [i] ] [ -
k k ] [ +|-L [l] ] [ +|-m m
      ] [ +|-M ] [ -o [o] ] [ -p s ] [ +|-r [t[m<fmt>]] ] [ -s [p:s] ] [ -S [t] ] [ -T [t] ] [ -u s ] [ +|-w ] [ -x [fl] ] [ -z [z] ] [ -Z [Z] ]
[ -- ] [names]

DESCRIPTION
      Lsof revision 4.86 lists on its standard output file information about files opened by processes for the following UNIX dialects:

           Apple Darwin 9 and Mac OS X 10.[567]
           FreeBSD 4.9 and 6.4 for x86-based systems
           FreeBSD 8.2, 9.0 and 10.0 for AMD64-based systems
           Linux 2.1.72 and above for x86-based systems
           Solaris 9, 10 and 11

      (See the DISTRIBUTION section of this manual page for information on how to obtain the latest lsof revision.)

      An open file may be a regular file, a directory, a block special file, a character special file, an executing text reference, a library,  a
      stream  or  a  network  file (Internet socket, NFS file or UNIX domain socket.)  A specific file or all the files in a file system may be
      selected by path.
```
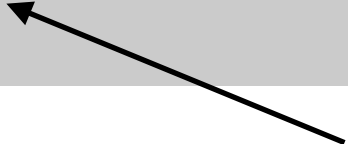

```
$ lsof
$ lsof -i | grep -i listen
$ lsof -i -P | grep -i listen
```

Handling Concurrency

Concurrency in Network Programming

You don't want your server to talk to only one client at the time, do you?

*Even for **stateless** protocols...*

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

blocking IO (synchronous)
n employee = n <u>threads</u>
employees are expensive
limited space for employees in the truck
few employees => long queue

non-blocking IO (asynchronous)
there is only 1 employee (1 thread)
customers are <u>called back</u> when the request is fulfilled
no queue

Concurrent Programming

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

- On top of the **operating system**, it is possible launch the Java Virtual Machine (**JVM**) several times (by invoking the java command). In this scenario, there is **one process (program) for every JVM instance**.

- If you don't do anything special, there is a **single execution thread** within each JVM. This means that all instructions in your code are executed **sequentially**.

- Very often, you write software where you want to **perform several tasks at the same time** (concurrently). For instance:

  - Manage a UI **while** fetching data from the network,

  - Talking to one HTTP client **while** talking to another HTTP client,

  - Have a worker do complex calculations on a subset of the data, **while** having another worker do the same calculations on another subset.

- You can use **threads** (also called **lightweight processes**) for this purpose.

Concurrent Programming in Java

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

- In Java, there are two main types

    - The **Thread class**, which *could be extended* to implement the behavior you want to run in parallel.

    - The **Runnable interface**, which *is implemented* for the same purpose and is passed as an argument to the Thread constructor.

```
┌─────────────────────────────────┐        ┌─────────────────────────────────┐
│           <<class>>             │        │          <<interface>>          │
│            Thread               │        │            Runnable             │
├─────────────────────────────────┤        ├─────────────────────────────────┤
│ Thread(Runnable runnable);      │        │                                 │
│ void start();                   │────────│ void run();                     │
│ static void sleep(long ms);     │        │                                 │
└─────────────────────────────────┘        └─────────────────────────────────┘
```

```
Worker worker = new Worker();
Thread t1 = new Thread(worker);
t1.start();

// at this point, Worker.run()
// will execute on thread t1.
```

```
┌─────────────────────────────────┐
│           <<class>>             │
│            Worker               │
├─────────────────────────────────┤
│                                 │
│ void run();                     │
│                                 │
└─────────────────────────────────┘
```

Concurrent Programming in Java

heig-vd
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud

- There are other classes related to threads, in the java.util.concurrent package. An important one is the **ExecutorService**, which makes it possible to use **thread pools**.

- A thread pool gives you a way to limit the number of threads spawned (by your server), so that you will not consume all resources. Others are queued.

http://www.vogella.com/ tutorials/ JavaConcurrency/ article.html

```java
package de.vogella.concurrency.threadpools;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
public class Main {
  private static final int NTHREDS = 10;

  public static void main(String[] args) {
    ExecutorService executor = Executors.newFixedThreadPool(NTHREDS);
    for (int i = 0; i < 500; i++) {
      Runnable worker = new MyRunnable(10000000L + i);
      executor.execute(worker);
    }
    // This will make the executor accept no new threads
    // and finish all existing threads in the queue
    executor.shutdown();
    // Wait until all threads are finish
    executor.awaitTermination();
    System.out.println("Finished all threads");
  }
}
```

Single Threaded
Single Process
Blocking

Not really an option...

The server implements a loop.

It waits for a client to arrive.
Then services the client until done.

Then only goes back to accept the next client.

Can only talk to 1 client at the time

It is only when we reach this line that a new client can connect

```
serverSocket = new ServerSocket(port);
while (true) {

    clientSocket = serverSocket.accept();

    in = new BufferedReader(new
    InputStreamReader(clientSocket.getInputStream()));
    out = new PrintWriter(clientSocket.getOutputStream());
    String line;
    boolean shouldRun = true;

    LOG.info("Reading until client sends BYE");

    while ( (shouldRun) && (line = in.readLine()) != null ) {
        if (line.equalsIgnoreCase("bye")) {
            shouldRun = false;
        }
        out.println("> " + line.toUpperCase());
        out.flush();
    }
    clientSocket.close();
    in.close();
    out.close();
}
```

It takes a long time to serve each client

**Single Threaded
Multi Process
Blocking**

How apache httpd did it
(with pre-fork, kind of...)

The server implements a loop.
It waits for a client to arrive.
When the client arrives, the server forks
a new process.

The child process serves the client while
the server is immediately ready to
serve the next client.

Forking a process is kind of heavy...
and resource hungry

While the child process serves the client...

... the parent can immediately welcome the next client.

```
while(1) {  // main accept() loop
    sin_size = sizeof their_addr;
    new_fd = accept(sockfd, (struct sockaddr *)&their_addr,
&sin_size);
    if (new_fd == -1) {
        perror("accept");
        continue;
    }

    inet_ntop(their_addr.ss_family,
        get_in_addr((struct sockaddr *)&their_addr),
        s, sizeof s);
    printf("server: got connection from %s\n", s);

    if (!fork()) { // this is the child process
        close(sockfd); // child doesn't need the listener
        if (send(new_fd, "Hello, world!", 13, 0) == -1)
            perror("send");
        close(new_fd);
        exit(0);
    }
    close(new_fd);  // parent doesn't need this
}
```

Multi Threaded
Single Process
Blocking

The 'old' Java way

The server uses a first thread to wait for
connection requests from clients.

Each time a client arrives, a new thread
is created and used to serve the client.

Millions of clients, millions of threads?

**Resource hungry.
Not scalable.**

```java
private class ReceptionistWorker implements Runnable {

    @Override
    public void run() {
        ServerSocket serverSocket;

        try {
            serverSocket = new ServerSocket(port);
        } catch (IOException ex) {
            LOG.log(Level.SEVERE, null, ex);
            return;
        }

        while (true) {
            LOG.log(Level.INFO, "Waiting for a new client");
            try {
                Socket clientSocket = serverSocket.accept();
                LOG.info("A new client has arrived...");
                new Thread(new ServantWorker(clientSocket)).start();
            } catch (IOException ex) {
                LOG.log(Level.SEVERE, ex.getMessage(), ex);
            }
        }
    }
}
```

As soon as a client is connected, a new thread is created.
The code that manages the interaction with the client executes on this thread.

2 types of workers, n+1 threads

Example: **07-TcpServers**

Single Thread
Single Process
Asynchronous Programming

We are registering callback functions on the various types of events that can be notified by the server...

The 'à la Node.js' way

The server uses a single thread, but in a non-blocking, asynchronous way.

Callback functions have to be written, so that they can be invoked when clients arrive, when data is received, etc.

Different programming logic.
Scalable.

```javascript
// let's create a TCP server
var server = net.createServer();

// it reacts to events: 'listening', 'connection', 'close', etc.
// register callback functions, to be invoked when the events
// occur (everything happens on the same thread)

server.on('listening', callbackFunctionToCallWhenSocketIsBound);
server.on('connection',
callbackFunctionToCallWhenNewClientHasArrived);

//Start listening on port 9907
server.listen(9907);

// This callback is called when the socket is bound and is in
// listening mode. We don't need to do anything special.
function callbackFunctionToCallWhenSocketIsBound() {
    console.log("The socket is bound and listening");
    console.log("Socket value: %j", server.address());
}

// This callback is called after a client has connected.
function callbackFunctionToCallWhenNewClientHasArrived(socket) {
  ...
}
```

... and we code these functions, implementing the behavior that is expected when the events occur.

Single Thread
Single Process
IO Multiplexing

The 'select' way

Sockets are set in a non-blocking state, which means that read(), write() and other functions do not block.

System calls such as select() or poll() block, but work on multiple sockets. They return if data has arrived on at least one of the sockets.

Watch out for performance.

Select is a blocking operation (with a possible timeout). It blocks until something has happened on one of the provided sets of file descriptors.

```c
#include <stdio.h>
#include <sys/time.h>
#include <sys/types.h>
#include <unistd.h>

int main(void) {
    fd_set rfds;
    struct timeval tv;
    int retval;

    /* Watch stdin (fd 0) to see when it has input. */
    FD_ZERO(&rfds);
    FD_SET(0, &rfds);
    /* Wait up to five seconds. */
    tv.tv_sec = 5;
    tv.tv_usec = 0;

    retval = select(1, &rfds, NULL, NULL, &tv);
    /* Don't rely on the value of tv now! */

    if (retval == -1)
        perror("select()");
    else if (retval)
        printf("Data is available now.\n");
        /* FD_ISSET(0, &rfds) will be true. */
    else
        printf("No data within five seconds.\n");

    return 0;
}
```

Here, we know that something has happened on one of the sockets. We can iterate over the set of file descriptors and get the data.

Example: **06-PresenceApplication**
